Proofs and Things

Why Logic?

- Computing, like mathematics, is the study of reusable abstractions.
- Abstractions in computing include numbers, lists, channels, processes, protocols, and programming languages.
- These abstractions have algorithmic value in designing, representing, and reasoning about computational processes.
- Properties of abstractions are captured by precisely stated laws through *formalization* using axioms, definitions, theorems, and proofs.
- Logic is the *medium* for expressing these abstract laws and the *method* for deriving consequences of these laws using sound reasoning principles.
- Computing is *abstraction engineering*.
- Logic is the calculus of computing.

The Unreasonable Effectiveness of Logic in Computing

- The world is increasingly an interplay of abstractions'
- Caches, files, IP addresses, avatars, friends, likes, hyperlinks, packets, network protocols, and cyber-physical systems are all examples of abstractions in daily use.
- Such abstract entities and the relationships can be expressed clearly and precisely in logic.
- In computing, and elsewhere, we are becoming increasingly dependent on formalization as a way of managing the abstract universe.

Where Logic has Been Effective

Logic has been *unreasonably* effective in computing, with an impact that spans

- Theoretical computer science: Algorithms, Complexity, Descriptive Complexity
- Hardware design and verification: Logic design, minimization, synthesis, model checking
- Software verification: Specification languages, Assertional verification, Verification tools
- Computer security: Information flow, Cryptographic protocols
- Programming languages: Logic/functional programming, Type systems, Semantics
- Artificial intelligence: Knowledge representation, Planning
- Databases: Data models, Query languages
- Systems biology: Process models

Our course is about the effective use of logic in computing.

- In mathematics, logic is studied as a source of interesting (meta-)theorems, but the reasoning is typically informal.
- In philosophy, logic is studied as a minimal set of foundational principles from which knowledge can be derived.
- In computing, the challenge is to solve large and complex problems through abstraction and decomposition.
- Formal, logical reasoning is needed to achieve scale and correctness.
- We will examine how logic is used to formulate problems, find solutions, and build proofs.
- We will also examine useful metalogical properties of logics, as well as algorithmic methods for effective inference.

- The course is spread over Four lectures:
 - **Lecture 1:** Proofs and Things
 - **Lecture 2:** Propositional Logics
 - **Lecture 3:** First-Order and Higher-Order Logic
 - **Lecture 4:** Advanced topics
- The goal is to learn how to speak logic fluently through the use of propositional, modal, equational, first-order, and higher-order logic.
- This will serve as a background for the more sophisticated ideas in the main lectures in the school.
- To get the most out of the course, please do the exercises.

A Small Puzzle [Wason]

- Given four cards laid out on a table as: \boxed{D} , $\boxed{3}$, \boxed{F} , $\boxed{7}$, where each card has a letter on one side and a number on the other.
- Which cards should you flip over to determine if every card with a \boxed{D} on one side has a $\boxed{7}$ on the other side?

A Small Problem

Given a bag containing some black balls and white balls, and a stash of black/white balls. Repeatedly

- 1 Remove a random pair of balls from the bag
- 2 If they are the same color, insert a white ball into the bag
- 3 If they are of different colors, insert a black ball into the bag

What is the color of the last ball?

Truth-tellers and Liars [Smullyan]

- You are confronted with two gates.
- One gate leads to the castle, and the other leads to a trap
- There are two guards, one at each gate: one always tells the truth, and the other always lies.
- You are allowed to ask one of the guards on question with a yes/no answer.
- What question should you ask in order to find out which gate leads to the castle?

When is Cheryl's Birthday?

- Albert and Bernard have just become friends with Cheryl, and they want to know her date of birth. Cheryl gives them 10 possible dates:

May 15 May 16 May 19

June 17 June 18

- July 14 July 16

August 14 August 15 August 17

- Cheryl then tells Albert and Bernard separately the month and the day of her birthday, respectively.
- **Albert:** I don't know when Cheryl's birthday is, but I know that Bernhard does not know too.
Bernard: At first I didn't know Cheryl's birthday, but now I do.
Albert: Then I also know Cheryl's birthday.
- When is Cheryl's birthday?

- Two integers m and n are picked from the interval $[2, 99]$.
- Mr. S is given the sum $m + n$. and Mr. P is given the product mn .
- They then have the following dialogue:
 - S:** *I don't know m and n .*
 - P:** *Me neither.*
 - S:** *I know that you don't.*
 - P:** *In that case, I do know m and n .*
 - S:** *Then, I do too.*
- How would you determine the numbers m and n ?

Pigeonhole Principle & Cantor's Theorem

- Why can't you park $n + 1$ cars in n parking spaces, if each car needs its own space?
- Let $m..n$ represent the subrange of integers from m to, but not including, n .
- An injection from set A to set B is a map f such that $f(x) = f(y)$ implies $x = y$, for any x, y in A .
- The Pigeonhole principle can be restated as asserting that there is no injection from $0..n + 1$ to $0..n$. Prove it.
- Let \mathbb{N} be the set of natural numbers $0, 1, 2, \dots$, and let $\wp(\mathbb{N})$ be the set of subsets of \mathbb{N} .
- Show that there is no injection from $\wp(\mathbb{N})$ to \mathbb{N} .

Gilbreath's Card Trick

- Start with a deck consisting of a stack of quartets, where the cards in each quartet appear in suit order ♠, ♥, ♣, ♦:

$\langle 5♠ \rangle, \langle 3♥ \rangle, \langle Q♣ \rangle, \langle 8♦ \rangle,$
 $\langle K♠ \rangle, \langle 2♥ \rangle, \langle 7♣ \rangle, \langle 4♦ \rangle,$
 $\langle 8♠ \rangle, \langle J♥ \rangle, \langle 9♣ \rangle, \langle A♦ \rangle$

- Cut the deck, say as $\langle 5♠ \rangle, \langle 3♥ \rangle, \langle Q♣ \rangle, \langle 8♦ \rangle, \langle K♠ \rangle$ and $\langle 2♥ \rangle, \langle 7♣ \rangle, \langle 4♦ \rangle, \langle 8♠ \rangle, \langle J♥ \rangle, \langle 9♣ \rangle, \langle A♦ \rangle$.
- Reverse one of the decks as $\langle K♠ \rangle, \langle 8♦ \rangle, \langle Q♣ \rangle, \langle 3♥ \rangle, \langle 5♠ \rangle$.
- Now shuffling, for example, as

$\langle 2♥ \rangle, \langle 7♣ \rangle, \underline{\langle K♠ \rangle}, \underline{\langle 8♦ \rangle},$
 $\langle 4♦ \rangle, \langle 8♠ \rangle, \underline{\langle Q♣ \rangle}, \underline{\langle J♥ \rangle},$
 $\underline{\langle 3♥ \rangle}, \underline{\langle 9♣ \rangle}, \underline{\langle 5♠ \rangle}, \underline{\langle A♦ \rangle}$

- Each quartet contains a card from each suit. Why?*

A Sorting Card Trick

- Arrange 25 cards from a deck of cards in a 5x5 grid.
- First, sort each of the rows individually.
- Then, sort each of the columns individually.
- Now both the rows and columns are sorted. How come?

Length of the Longest Increasing Subsequence

- You have a sequence of numbers, e.g.,
9, 7, 10, 9, 5, 4, 10.
- The task is to find the length of the longest increasing subsequence.
- Here the longest subsequence is 7, 9, 10, and its length is 3.
- Patience solitaire is a card game where cards are placed, one by one, into a sequence of columns.
- Each card is placed at the bottom of the leftmost column where it is no bigger than the current bottom card in the column.
- If there is no such column, we start a new column at the right.
- Show that the number of columns left at the end yields the length of the longest increasing subsequence.

Computing Majority

- An election has five candidates: Alice, Bob, Cathy, Don, and Ella.
- The votes have come in as:
E, D, C, B, C, C, A, C, E, C, A, C, C.
- You are told that some candidate has won the majority (over half) of the votes.
- You successively remove pairs of dissimilar votes, until there are no more such pairs.
- That is, the remaining votes, if any, are all for the same candidate.
- Show that this candidate has the majority.

Propositional Logic

What is Logic?

- Logic is the art and science of effective reasoning.
- How can we draw general and reliable conclusions from a collection of facts?
- Formal logic: Precise, syntactic characterizations of well-formed expressions and valid deductions.
- Formal logic makes it possible to *calculate* consequences so that each step is verifiable by means of proof.
- **Computers can be used to automate such symbolic calculations.**

Naïve Set Theory

- We will be using sets informally in talking about logic.
- Sets have members $x \in X$, and can be related through equality $X = Y$ and subset $X \subset Y$ or $X \subseteq Y$.
- Sets include the emptyset \emptyset , the singleton set $\{a\}$ containing just a as an element, the two-element set $\mathbf{2} = \{0, 1\}$, the set \mathbb{N} of natural numbers $\{0, 1, 2, \dots\}$.
- Other examples include the set of integers, odd integers, even integers, prime numbers, rational numbers, algebraic numbers, real numbers, etc.
- The set of elements satisfying a property P is represented as $\{x|P(x)\}$, e.g., $\{i|0 \leq i \leq 5\}$.
- The $\{F(x)|P(x)\}$ contains all and only the elements $F(a)$ for each element a satisfying $P(a)$, e.g., $\{x^2|0 \leq x \leq 5\}$.
- Let X^Y represent the set of functions with Y as domain and X as range.
- 2^X is the power set of X $\{Y|Y \subseteq X\}$.

Naïve Set Theory

- The set $\{a, b\}$ represents the set that is the pair of elements a and b , which can themselves be sets.
- Ordered pairing $\langle x, y \rangle$ can be represented as $\{\{a, b\}, \{b\}\}$.
- The union $\bigcup X$ is the set $\{x \mid x \in y, y \in X\}$. $X \cup Y$ is just $\bigcup\{X, Y\}$.
- The intersection $\bigcap X$ is the set $\{x \mid x \in y, \text{ for each } y \in X\}$. $X \cap Y$ is just $\bigcap\{X, Y\}$.
- The relative complement $X - Y$ of two sets is the set $\{x \mid x \in X, x \notin Y\}$.
- The Cartesian product $X \times Y$ is the set of ordered pairs $\langle x, y \rangle$ for $x \in X$ and $y \in Y$.
- Two sets are equal if they have exactly the same elements. Prove $(X \cup Y) \cup Z = X \cup (Y \cup Z)$, $X \cup Y = Y \cup X$, $X \cup X = X$, and similarly for intersection.

- The set of integers \mathbb{Z} is $\{\dots, -3, -2, -1, 0, 1, 2, 3, \dots\}$.
- A map F between X and Y is injective if whenever $F(x) = F(x')$ for x, x' in X , we have $x = x'$.
- A map F between X and Y is surjective if for each $y \in Y$, there is an $x \in X$, such that $F(x) = y$.
- A map F between X and Y is a bijection if F is both injective and surjective.
- The *graph* of a map F between X and Y can be represented as a subset of $X \times Y$ as $\{\langle x, y \rangle \mid F(x) = y\}$.
- A subset G of $X \times Y$ is a graph if for any $x \in X$, there is exactly one y such that $\langle x, y \rangle \in G$.

- One set is *equinumerous* with another if there is a bijection between them.
- *Is the set \mathbb{Z} equinumerous with \mathbb{N} .*
- *Can a set X be equinumerous with its powerset 2^X ?*
- *Is the set of rational numbers \mathbb{Q} equinumerous with \mathbb{N} ?*
- *Is the set of real numbers in the interval $[0, 1]$ equinumerous with \mathbb{N} ?*

Ordinal Numbers

- A set X is *well-ordered* if there is an order relation $x < y$ between elements x and y of X such that every nonempty subset of X has a least element.
- The ordinal numbers can be constructed as: 0 is an ordinal number, and the next ordinal number is the set of all preceding ordinal numbers.
- The ordinals are well-ordered, and any well-ordered set is order-isomorphic, i.e., has an order-preserving bijection, to some ordinal,
- *Is the set \mathbb{N} under the usual $<$ ordering of natural numbers well ordered?*
- *Is the set \mathbb{Z} under the usual $<$ ordering of integers well ordered? Is there a well ordering for \mathbb{Z} ?*
- *Is the set \mathbb{Q} under the usual $<$ ordering of rationals well ordered? Is there a well ordering for \mathbb{Q} ?*

- Let ω represent the ordinal number for \mathbb{N} with $0 < 1 < 2 \dots$
- \mathbb{N} can be ordered so that $i < j$ for any even number i and odd number j to get $0 < 2 < 4 \dots 1 < 3 < 5 \dots$
- This has the order type $\omega + \omega$.
- A lexicographic ordering on $\mathbb{N} \times \mathbb{N}$ has $\langle x, y \rangle < \langle x', y' \rangle$ if $x < x'$, or $x = x'$ and $y < y'$, e.g., $\langle 5, 3 \rangle < \langle 5, 4 \rangle$.
- *What is the ordinal corresponding to the above lexicographic ordering?*
- *Can you define an ordering on \mathbb{N} that is order isomorphic to the lexicographic ordering on $\mathbb{N} \times \mathbb{N}$.*

- The Liar paradox has the Cretan Epimenides asserting that *All Cretans are liars.*? *Is Epimenides telling the truth?*
- Berry's paradox: What is "the smallest natural number that is not definable in fewer than twelve words"?
- Richards paradox: Let p_0, p_1, \dots , be an enumeration of the properties of natural numbers. We say that i is *Richardian* if $\neg p_i(i)$. Is there a property p_r in the enumeration that captures the property of being Richardian?
- *Let R be the set $\{x|x \notin x\}$. Is $R \in R$?*
- *Is there a universal set V given by $\{x|x = x\}$?*
- *The set of ordinals **ON** is well-ordered? Is **ON** \in **ON**?*

- Logic studies the *trinity* between *language*, *interpretation*, and *proof*.
- *Language*: What are you allowed to say?
- *Interpretation*: What is the intended meaning?
 - Meaning is usually *compositional*: Follows the syntax
 - Some symbols have fixed meaning: **connectives**, **equality**, **quantifiers**
 - Other symbols are allowed to vary **variables**, **functions**, and **predicates**
 - *Assertions* either hold or fail to hold in a given interpretation
 - A *valid* assertion holds in every interpretation
- *Proofs* are used to demonstrate validity

- Propositional logic can be more accurately described as a logic of conditions – *propositions are always true or always false*. [Couturat, *Algebra of Logic*]
- A condition can be represented by a propositional variable, e.g., p , q , etc., so that distinct propositional variables can range over possibly different conditions.
- The conjunction, disjunction, and negation of conditions are also conditions.
- The syntactic representation of conditions is using propositional formulas:

$$\phi := P \mid \neg\phi \mid \phi_1 \vee \phi_2 \mid \phi_1 \wedge \phi_2$$

- P is a class of propositional variables: p_0, p_1, \dots
- Examples of formulas are p , $p \wedge \neg p$, $p \vee \neg p$, $(p \wedge \neg q) \vee \neg p$.

Meaning

- In logic, the meaning of an expression is constructed compositionally from the meanings of its subexpressions.
- The meanings of the symbols are either *fixed*, as with \neg , \wedge , and \vee , or allowed to *vary*, as with the propositional variables.
- An interpretation (truth assignment) M assigns truth values $\{\top, \perp\}$ to propositional variables: $M(p) = \top \iff M \models p$.
- $M[[A]]$ is the meaning of A in M and is computed using truth tables:

ϕ	p	q	$\neg p$	$p \vee q$	$p \wedge q$
$M_1(\phi)$	\perp	\perp	\top	\perp	\perp
$M_2(\phi)$	\perp	\top	\top	\top	\perp
$M_3(\phi)$	\top	\perp	\perp	\top	\perp
$M_4(\phi)$	\top	\top	\perp	\top	\top

Truth Tables

We can use truth tables to evaluate formulas for validity/satisfiability.

p	q	$(\neg p \vee q)$	$(\neg(\neg p \vee q) \vee p)$	$\neg(\neg(\neg p \vee q) \vee p) \vee p$
\perp	\perp	\top	\perp	\top
\perp	\top	\top	\perp	\top
\top	\perp	\perp	\top	\top
\top	\top	\top	\top	\top

How many rows are there in the truth table for a formula with n distinct propositional variables?

How many distinct truth tables are there in n distinct propositional variables?

- Define the operation of substituting a formula A for a variable p in a formula B , i.e., $B[p \mapsto A]$.
- Is the result always a well-formed formula?
- Can the variable p occur in $B[p \mapsto A]$?
- What is the truth-table meaning of $B[p \mapsto A]$ in terms of the meaning of B and A ?

Defining New Connectives

- How do you define \wedge in terms of \neg and \vee ?
- Give the truth table for $A \Rightarrow B$ and define it in terms of \neg and \vee .
- Define bi-implication $A \iff B$ in terms of \Rightarrow and \wedge and show its truth table.
- An n -ary Boolean function maps $\{\top, \perp\}^n$ to $\{\top, \perp\}$
- Show that every n -ary Boolean function can be defined using \neg and \vee .
- Using \neg and \vee define an n -ary parity function which evaluates to \top iff the parity is odd.
- Define an n -ary function which determines that the unsigned value of the little-endian input p_0, \dots, p_{n-1} is even?
- Define the *NAND* operation, where $NAND(p, q)$ is $\neg(p \wedge q)$ using \neg and \vee . Conversely, define \neg and \vee using *NAND*.

Satisfiability and Validity

- An interpretation M is a model of a formula ϕ if $M \models \phi$.
- If $M \models \neg\phi$, then M is a *countermodel* for ϕ .
- When ϕ has a model, it is said to be *satisfiable*.
- If it has no model, then it is *unsatisfiable*.
- If $\neg\phi$ is unsatisfiable, then ϕ is valid, i.e., always evaluates to \top .
- We write $\phi \models \psi$ if every model of ϕ is a model of ψ .
- If $\phi \wedge \neg\psi$ is unsatisfiable, then $\phi \models \psi$.

Satisfiable, Unsatisfiable, or Valid?

- Classify these formulas as satisfiable, unsatisfiable, or valid?
 - $p \vee \neg p$
 - $p \wedge \neg p$
 - $\neg p \Rightarrow p$
 - $((p \Rightarrow q) \Rightarrow p) \Rightarrow p$
- Make up some examples of formulas that are satisfiable (unsatisfiable, valid)?
- If A and B are satisfiable, is $A \wedge B$ satisfiable? What about $A \vee B$.
- Can A and $\neg A$ both be satisfiable (unsatisfiable, valid)?

Some Valid Laws

- A bi-implication $A \iff B$ is valid (and hence A and B are *equivalent*) iff every model of A is a model of B and vice-versa.
- Check that following formulas are valid for any assignment to A and B ?

- 1 $\neg(A \wedge B) \iff \neg A \vee \neg B$
- 2 $\neg(A \vee B) \iff \neg A \wedge \neg B$
- 3 $((A \vee B) \vee C) \iff A \vee (B \vee C)$
- 4 $(A \Rightarrow B) \iff (\neg A \vee B)$
- 5 $(\neg A \Rightarrow \neg B) \iff (B \Rightarrow A)$
- 6 $\neg\neg A \iff A$
- 7 $A \Rightarrow B \iff \neg A \vee B$
- 8 $\neg(A \wedge B) \iff \neg A \vee \neg B$
- 9 $\neg(A \vee B) \iff \neg A \wedge \neg B$
- 10 $\neg A \Rightarrow B \iff \neg B \Rightarrow A$

What Can Propositional Logic Express?

- Constraints over bounded domains can be expressed as satisfiability problems in propositional logic (SAT).
- Define a 1-bit full adder in propositional logic.
- The Pigeonhole Principle states that if $n + 1$ pigeons are assigned to n holes, then some hole must contain more than one pigeon. Formalize the pigeonhole principle for four pigeons and three holes.
- Formalize the statement that a graph of n elements is k -colorable for given k and n such that $k < n$.
- Formalize and prove the statement that given a symmetric and transitive graph over 3 elements, either the graph is complete or contains an isolated point.
- Formalize *Sudoku* and Latin Squares in propositional logic.

- Write a propositional formula for checking that a given finite automaton $\langle Q, \Sigma, q, F, \delta \rangle$ with
 - Alphabet Σ ,
 - Set of states S
 - Initial state q ,
 - Set of final states F , and
 - Transition function δ from $\langle Q, \Sigma \rangle$ to Qaccepts some string of length 5.
- Describe an N -bit ripple carry adder with a carry-in and carry-out bits as a formula.

- A Turing machine consists of a finite automaton reading (and writing) symbols from a finite set Σ (including a blank symbol ' $_$ ') from a tape $\dots, T(-1), T(0), T(1), \dots$
- Initially, the tape is blank except at the input $T(0), \dots, T(n-1)$.
- The finite automaton has a finite set of states Q , a subset F of which are accepting states.
- In each step, if the automaton is at a non-accepting state, the machine reads the symbol at the current position of the head, and nondeterministically executes a step consisting of
 - 1 A new symbol to write at the head position
 - 2 A move (left or right) of the head from the current position
 - 3 A next automaton state

Cook's Theorem

- For some bound N on the number of machine steps, show that it is possible to represent the following using a polynomial number (in n) of Boolean variables
 - 1 The k 'th symbol is on the i 'th cell in the j 'th state of the computation.
 - 2 The head is at the i 'th cell in the j 'th state of the computation.
 - 3 The automaton is in the m 'th state in the j 'th state of the computation.
- Show that SAT is solvable in polynomial time (in the size n of the input) by a nondeterministic Turing machine.
- Show that for any nondeterministic Turing machine and polynomial bound $p(n)$ for input of size n , one can (in polynomial time) construct a propositional formula which is satisfiable iff there is the Turing machine accepts the input in at most $p(n)$.

Reductions to SAT

- Encode the following problems as SAT problems
 - ① 3-colorability of an undirected graph.
 - ② The k -colorability for a given k .
 - ③ The existence of a Hamiltonian path in a graph, one that visits each vertex exactly once.
 - ④ The existence of a k -clique in a graph: a set of k vertices that are pairwise connected by edges.
- What is the size of your encoding?
- A problem is *NP-hard* if there is a polynomial-time (many-to-one, Turing, truth-table) reduction from SAT (or another NP-hard) problem to it.

- There are three basic styles of proof systems.
- These are distinguished by their basic judgement.
 - 1 Hilbert systems: $\vdash A$ means the formula A is provable.
 - 2 Natural deduction: $\Gamma \vdash A$ means the formula A is provable from a set of assumption formulas Γ .
 - 3 Sequent Calculus: $\Gamma \vdash \Delta$ means the consequence of $\bigvee \Delta$ from $\bigwedge \Gamma$ is derivable.

Hilbert System (H) for Propositional Logic

- The basic judgement here is $\vdash A$ asserting that a formula is *provable*.
- We can pick \Rightarrow as the basic connectives
- The axioms are
 - $\frac{}{\vdash A \Rightarrow A}$
 - $\frac{}{\vdash A \Rightarrow (B \Rightarrow A)}$
 - $\frac{}{\vdash (A \Rightarrow (B \Rightarrow C)) \Rightarrow ((A \Rightarrow B) \Rightarrow (A \Rightarrow C))}$
- A single rule of inference (Modus Ponens) is given

$$\frac{\vdash A \quad \vdash A \Rightarrow B}{\vdash B}$$

- Can you prove $((p \Rightarrow q) \Rightarrow p) \Rightarrow p$ using the above system?

Hilbert System (H)

- Add a propositional constant \perp to the formula syntax, where $\llbracket \perp \rrbracket = \perp$.
- Define negation $\neg A$ as $A \Rightarrow \perp$.
- Can you prove
 - 1 $\neg A \Rightarrow (A \Rightarrow \neg B)$
 - 2 $\neg A \Rightarrow (A \Rightarrow \perp)$
 - 3 $\neg\neg A \Rightarrow A$
- Are any of the axioms redundant? [Hint: See if you can prove the first axiom from the other two.]
- Write Hilbert-styel axioms for \wedge and \vee .

Deduction Theorem

- We write $\Gamma \vdash A$ for a set of formulas Γ , if $\vdash A$ can be proved given $\vdash B$ for each $B \in \Gamma$.
- Deduction theorem: Show that if $\Gamma, A \vdash B$, then $\Gamma \vdash A \Rightarrow B$, where Γ, A is $\Gamma \cup \{A\}$. [Hint: Use induction on proofs.]
- A *derived* rule of inference has the form

$$\frac{P_1, \dots, P_n}{C}$$

where there is a derivation in the base logic from the premises P_1, \dots, P_n to the conclusion C .

- An *admissible* rule of inference is one where the conclusion C is provable if the premises P_1, \dots, P_n are provable.
- Every derived rule is admissible, but what is an example of an admissible rule that is not a derived one?

Natural Deduction for Propositional Logic

- In natural deduction (ND), the basic judgement is $\Gamma \vdash A$.
- The rules are classified according to the introduction or elimination of connectives from A in $\Gamma \vdash A$.
- The axiom, introduction, and elimination rules of natural deduction are

- $$\frac{\overline{\Gamma, A \vdash A}}{\Gamma_1 \vdash A} \quad \Gamma_2 \vdash A \Rightarrow B}{\Gamma_1 \cup \Gamma_2 \vdash B}$$
- $$\frac{\Gamma, A \vdash B}{\Gamma \vdash A \Rightarrow B}$$

- Use ND to prove the axioms of the Hilbert system.
- A proof is in *normal form* if no introduction rule appears above an elimination rule. Can you ensure that your proofs are always in normal form? Can you write an algorithm to convert non-normal proofs to normal ones?

Sequent Calculus (LK) for Propositional Logic

The basic judgement is $\Gamma \vdash \Delta$ asserting that $\bigwedge \Gamma \Rightarrow \bigvee \Delta$, where Γ and Δ are sets (or bags) of formulas.

	Left	Right
Ax	$\frac{}{\Gamma, A \vdash A, \Delta}$	
\neg	$\frac{\Gamma \vdash A, \Delta}{\Gamma, \neg A \vdash \Delta}$	$\frac{\Gamma, A \vdash \Delta}{\Gamma \vdash \neg A, \Delta}$
\vee	$\frac{\Gamma, A \vdash \Delta \quad \Gamma, B \vdash \Delta}{\Gamma, A \vee B \vdash \Delta}$	$\frac{\Gamma \vdash A, B, \Delta}{\Gamma \vdash A \vee B, \Delta}$
\wedge	$\frac{\Gamma, A, B \vdash \Delta}{\Gamma, A \wedge B \vdash \Delta}$	$\frac{\Gamma \vdash A, \Delta \quad \Gamma \vdash B, \Delta}{\Gamma \vdash A \wedge B, \Delta}$
\Rightarrow	$\frac{\Gamma, B \vdash \Delta \quad \Gamma \vdash A, \Delta}{\Gamma, A \Rightarrow B \vdash \Delta}$	$\frac{\Gamma, A \vdash B, \Delta}{\Gamma \vdash A \Rightarrow B, \Delta}$
Cut	$\frac{\Gamma \vdash A, \Delta \quad \Gamma, A \vdash \Delta}{\Gamma \vdash \Delta}$	

- A sequent calculus proof of Peirce's formula $((p \Rightarrow q) \Rightarrow p) \Rightarrow p$ is given by

$$\frac{\frac{\frac{\overline{p \vdash p, q} \text{ Ax}}{\vdash p, p \Rightarrow q} \text{ } \vdash \Rightarrow}{(p \Rightarrow q) \Rightarrow p \vdash p} \Rightarrow \vdash}{\vdash ((p \Rightarrow q) \Rightarrow p) \Rightarrow p} \vdash \Rightarrow$$

- The sequent formula that is introduced in the conclusion is the *principal* formula, and its components in the premise(s) are *side* formulas.

- Metatheorems about proof systems are useful in providing reasoning short-cuts.
- The deduction theorem for H and the normalization theorem for ND are examples.
- Prove that the Cut rule is admissible for the LK . (Difficult!)
- A bi-implication is a formula of the form $A \iff B$, and it is an equivalence when it is valid. Show that the following is a derived inference rule.

$$\frac{A \iff B}{C[p \mapsto A] \iff C[p \mapsto B]}$$

- State a similar rule for implication where

$$\frac{A \Rightarrow B}{C[p \mapsto A] \Rightarrow C[p \mapsto B]}$$

Normal Forms for Formulas

- A formula where negation is applied only to propositional atoms is said to be in negation normal form (NNF).
- For example, $\neg(p \vee \neg q)$ can be represented as $\neg p \wedge q$.
- Show that every propositional formula built using \neg , \vee , and \wedge is equivalent to one in NNF.
- A *literal* l is either a propositional atom p or its negation $\neg p$.
- A *clause* is a multiary disjunction of a set of literals $l_1 \vee \dots \vee l_n$.
- A multiary conjunction of n formulas A_1, \dots, A_n is $\bigwedge_{i=1}^n A_i$.

Conjunctive and Disjunctive Normal Forms

- A formula that is a multiary conjunction of multiary disjunctions of literals is in conjunctive normal form (CNF).
- CNF Example:
$$\begin{aligned} & (\neg p \vee q \vee \neg r) \\ & \wedge (p \vee r) \\ & \wedge (\neg p \vee \neg q \vee r) \end{aligned}$$
- Define an algorithm for converting any propositional formula to CNF.
- A formula is in k -CNF if it uses at most k literals per clause. Define an algorithm for converting any formula to 3-CNF.
- A formula that is a multiary disjunction of multiary conjunctions of literals is in disjunctive normal form (DNF).
- Define an algorithm for converting any formula to DNF.

- A proof system is *sound* if all provable formulas are valid, i.e., $\vdash A$ implies $\models A$, i.e., $M \models A$ for all M .
- To prove soundness, show that for any inference rule of the form

$$\frac{\vdash P_1, \dots, \vdash P_n}{\vdash C},$$

any model of all of the premises is also a model of the conclusion.

- Since the axioms are valid, and each step preserves validity, we have that the conclusion of a proof is also valid.
- **Demonstrate the soundness of the proof systems shown so far, i.e.,**
 - 1 Hilbert system H
 - 2 Natural deduction ND
 - 3 Sequent Calculus LK

- A proof system is *complete* if all valid formulas are provable, i.e., $\models A$ implies $\vdash A$.
- A countermodel M of $\Gamma \vdash \Delta$ is one where either $M \models A$ for all A in Γ , and $M \models \neg B$ for all $B \in \Delta$.
- In LK , any countermodel of some premise of a rule is also a countermodel for the conclusion. *What is the countermodel for $p \vee q \vdash p \wedge q$?*
- We can then show that a non-provable sequent $\Gamma \vdash \Delta$ has a countermodel.
- Each non-Cut rule has premises that are simpler than its conclusion.
- By applying the rules starting from $\Gamma \vdash \Delta$ to completion, you end up with a set of premise sequents $\{\Gamma_1 \vdash \Delta_1, \dots, \Gamma_n \vdash \Delta_n\}$ that are *atomic*, i.e., that contain no connectives.
- If an atomic sequent $\Gamma_i \vdash \Delta_i$ is unprovable, then it has a countermodel, i.e., one in which each formula in Γ_i holds but no formula in Δ_i holds.

Completeness, More Generally

- A set of formulas Γ is *consistent*, i.e., $Con(\Gamma)$ iff there is no formula A in Γ such that $\Gamma \vdash \neg A$ is provable.
- If Γ is consistent, then $\Gamma \cup \{A\}$ is consistent iff $\Gamma \vdash \neg A$ is not provable.
- If Γ is consistent, then at least one of $\Gamma \cup \{A\}$ or $\Gamma \cup \{\neg A\}$ must be consistent.
- A set of formulas Γ is *complete* if for each formula A , it contains A or $\neg A$.

- Any consistent set of formulas Γ can be made complete as $\hat{\Gamma}$.
- Let A_i be the i 'th formula in some enumeration of PL formulas. Define

$$\begin{aligned}\Gamma_0 &= \Gamma \\ \Gamma_{i+1} &= \Gamma_i \cup \{A_i\}, \text{ if } \text{Con}(\Gamma_i \cup \{A_i\}) \\ &= \Gamma_i \cup \{\neg A_i\}, \text{ otherwise.} \\ \hat{\Gamma} &= \Gamma_\omega = \bigcup_i \Gamma_i\end{aligned}$$

- Ex: Check that $\hat{\Gamma}$ yields an interpretation $\mathcal{M}_{\hat{\Gamma}}$ satisfying Γ .
- If $\Gamma \vdash \Delta$ is unprovable, then $\Gamma \cup \overline{\Delta}$ is consistent, and has a model.

- A logic is *compact* if any set of sentences Γ is satisfiable iff all finite subsets of it are, i.e., if it is *finitely satisfiable*.
- Propositional logic is compact — hard direction is showing that every finitely satisfiable set is satisfiable.
- Zorn's lemma states that if in a partially ordered set A , every chain L has an upper bound \hat{L} in A , then A has a maximal element.
- Given a finitely satisfiable set Γ , the set of finitely satisfiable extensions satisfies the conditions of Zorn's lemma.
- Hence there is a maximal extension $\hat{\Gamma}$ that is finitely satisfiable.
- For any atom p , exactly $p \in \hat{\Gamma}$ or $\neg p \in \hat{\Gamma}$. Why?
- We can similarly define the model $M_{\hat{\Gamma}}$ to show that $\hat{\Gamma}$ is satisfiable.

Craig's interpolation property states that given two sets of formulas Γ_1 and Γ_2 in propositional variables Σ_1 and Σ_2 , respectively, $\Gamma_1 \cup \Gamma_2$ is unsatisfiable iff there is a formula A in propositional variables $\Sigma_1 \cap \Sigma_2$ such that $\Gamma_1 \models A$ and Γ_2, A is unsatisfiable.

A_{x_1}	$\frac{}{[\perp] \vdash \Gamma, P, \bar{P}; \Delta}$
A_{x_2}	$\frac{}{[\top] \vdash \Gamma; P, \bar{P}, \Delta}$
A_{x_3}	$\frac{}{[P] \vdash \Gamma, P; \bar{P}, \Delta}$
$\neg\neg$	$\frac{[I] \vdash P, \Delta}{[I] \vdash \neg\neg P, \Delta}$
\vee	$\frac{[I] \vdash A, B, \Delta}{[I] \vdash A \vee B, \Delta}$
$\neg\vee_1$	$\frac{[I_1] \vdash \Gamma, \neg A; \Delta \quad [I_2] \vdash \Gamma, \neg B; \Delta}{[[I_1 \vee I_2] \vdash \Gamma, \neg(A \vee B); \Delta]}$
$\neg\vee_2$	$\frac{[I_1] \vdash \Gamma; \neg A, \Delta \quad [I_2] \vdash \Gamma; \neg B, \Delta}{[I_1 \wedge I_2] \vdash \Gamma; \neg(A \vee B), \Delta}$

- We have already seen that any propositional formula can be written in CNF as a conjunction of clauses.
- Input K is a set of clauses.
- Tautologies, i.e., clauses containing both l and \bar{l} , are deleted from initial input.

Res	$\frac{K, l \vee \Gamma_1, \bar{l} \vee \Gamma_2}{K, l \vee \Gamma_1, \bar{l} \vee \Gamma_2, \Gamma_1 \vee \Gamma_2} \quad \Gamma_1 \vee \Gamma_2 \notin K$ $\Gamma_1 \vee \Gamma_2 \text{ is not tautological}$
Contrad	$\frac{K, l, \bar{l}}{\perp}$

Resolution: Example

$$\begin{array}{r} (K_0 =) \neg p \vee \neg q \vee r, \neg p \vee q, p \vee r, \neg r \\ \hline (K_1 =) \neg q \vee r, K_0 \\ \hline (K_2 =) q \vee r, K_1 \\ \hline (K_3 =) r, K_2 \\ \hline \perp \end{array} \begin{array}{l} \text{Res} \\ \text{Res} \\ \text{Res} \\ \text{Contrad} \end{array}$$

Show that resolution is a sound and complete procedure for checking satisfiability.

- Goal: Does a given set of clauses K have a satisfying assignment?
- If M is a total assignment such that $M \models \Gamma$ for each $\Gamma \in K$, then $M \models K$.
- If M is a partial assignment at level h , then *propagation* extends M at level h with the *implied literals* l such that $l \vee \Gamma \in K \cup C$ and $M \models \neg \Gamma$.
- If M detects a conflict, i.e., a clause $\Gamma \in K \cup C$ such that $M \models \neg \Gamma$, then the conflict is *analyzed* to construct a conflict clause that allows the search to be continued from a prior level.
- If M cannot be extended at level h and no conflict is detected, then an unassigned literal l is *selected* and assigned at level $h + 1$ where the search is continued.

Conflict-Driven Clause Learning (CDCL) SAT

Name	Rule	Condition
Propagate	$\frac{h, \langle M \rangle, K, C}{h, \langle M, I[\Gamma] \rangle, K, C}$	$\Gamma \equiv I \vee \Gamma' \in K \cup C$ $M \models \neg \Gamma'$
Select	$\frac{h, \langle M \rangle, K, C}{h + 1, \langle M; I[\] \rangle, K, C}$	$M \not\models I$ $M \not\models \neg I$
Conflict	$\frac{0, \langle M \rangle, K, C}{\perp}$	$M \models \neg \Gamma$ for some $\Gamma \in K \cup C$
Backjump	$\frac{h + 1, \langle M \rangle, K, C}{h', \langle M_{\leq h'}, I[\Gamma'] \rangle, K, C \cup \{\Gamma'\}}$	$M \models \neg \Gamma$ for some $\Gamma \in K \cup C$ $\langle h', \Gamma' \rangle$ $= \text{analyze}(\psi)(\Gamma)$ for $\psi = h, \langle M \rangle, K, C$

- Let K be
 $\{p \vee q, \neg p \vee q, p \vee \neg q, s \vee \neg p \vee q, \neg s \vee p \vee \neg q, \neg p \vee r, \neg q \vee \neg r\}$.
-

step	h	M	K	C	Γ
select s	1	$; s$	K	\emptyset	-
select r	2	$; s; r$	K	\emptyset	-
propagate	2	$; s; r, \neg q[\neg q \vee \neg r]$	K	\emptyset	-
propagate	2	$; s; r, \neg q, p[p \vee q]$	K	\emptyset	-
conflict	2	$; s; r, \neg q, p$	K	\emptyset	$\neg p \vee q$

CDCL Example (contd.)

step	h	M	K	C	Γ
conflict	2	$; s; r, \neg q, p$	K	\emptyset	$\neg p \vee q$
backjump	0	\emptyset	K	q	-
propagate	0	$q[q]$	K	q	-
propagate	0	$q, p[p \vee \neg q]$	K	q	-
propagate	0	$q, p, r[\neg p \vee r]$	K	q	-
conflict	0	q, p, r	K	q	$\neg q \vee \neg r$

Show that CDCL is sound and complete.

- Boolean functions map $\{0, 1\}^n$ to $\{0, 1\}$.
- We have already seen how n -ary Boolean functions can be represented by propositional formulas of n variables.
- ROBDDs are a canonical representation of boolean functions as a decision diagram where
 - 1 Literals are uniformly ordered along every branch:

$$f(x_1, \dots, x_n) = \text{IF}(x_1, f(\top, x_2, \dots, x_n), f(\perp, x_2, \dots, x_n))$$
 - 2 Common subterms are identified
 - 3 Redundant branches are removed: $\text{IF}(x_i, A, A) = A$
- Efficient implementation of boolean operations: $f_1 \cdot f_2$, $f_1 + f_2$, $\neg f$, including quantification.
- Canonical form yields free equivalence checks (for convergence of fixed points).

ROBDD for Even Parity

ROBDD for even parity boolean function of a, b, c .

Construct an algorithm to compute $f_1 \odot f_2$, where \odot is \wedge or \vee .
Construct an algorithm to compute $\exists \bar{x}.f$.

First and Higher-Order Logic

Equality Logic (EL)

In the process of creeping toward first-order logic, we introduce a modest but interesting extension of propositional logic.

In addition to propositional atoms, we add a set of constants τ given by c_0, c_1, \dots and equalities $c = d$ for constants c and d .

$$\phi := P \mid \neg\phi \mid \phi_1 \vee \phi_2 \mid \phi_1 \wedge \phi_2 \mid \tau_1 = \tau_2$$

The structure M now has a domain $|M|$ and maps propositional variables to $\{\top, \perp\}$ and constants to $|M|$.

$$M[c = d] = \begin{cases} \top, & \text{if } M[c] = M[d] \\ \perp, & \text{otherwise} \end{cases}$$

Proof Rules for Equality Logic

Reflexivity	$\Gamma \vdash a = a, \Delta$
Symmetry	$\frac{\Gamma \vdash a = b, \Delta}{\Gamma \vdash b = a, \Delta}$
Transitivity	$\frac{\Gamma \vdash a = b, \Delta \quad \Gamma \vdash b = c, \Delta}{\Gamma \vdash a = c, \Delta}$

- Show that the above proof rules (on top of propositional logic) are sound and complete.
- Show that Equality Logic is decidable.
- Adapt the above logic to reason about a partial ordering relation \leq , i.e., one that is reflexive, transitive, and anti-symmetric ($x \leq y \wedge y \leq x \Rightarrow x = y$).

Term Equality Logic (TEL)

- One further extension is to add function symbols from a signature Σ that assigns an arity to each symbol.
- Function symbols are used to form terms τ , so that constants are just 0-ary function symbols.

$$\tau := f(\tau_1, \dots, \tau_n), \text{ for } n \geq 0$$

$$\phi := P \mid \neg\phi \mid \phi_1 \vee \phi_2 \mid \phi_1 \wedge \phi_2 \mid \tau_1 = \tau_2$$

- For an n -ary function f , $M(f)$ maps $|M|^n$ to $|M|$.

$$M[a = b] = M[a] = M[b]$$

$$M[f(a_1, \dots, a_n)] = (M[f])(M[a_1], \dots, M[a_n])$$

- We need one additional proof rule.

Congruence	$\frac{\Gamma \vdash a_1 = b_1, \Delta \dots \Gamma \vdash a_n = b_n, \Delta}{\Gamma \vdash f(a_1, \dots, a_n) = f(b_1, \dots, b_n), \Delta}$
------------	---

Term Equality Proof Examples

Let $f^n(a)$ represent $f(\underbrace{\dots f(a)\dots}_n)$.

$$\frac{\frac{\frac{f^3(a) = f(a) \vdash f^3(a) = f(a)}{f^3(a) = f(a) \vdash f^4(a) = f^2(a)} C}{f^3(a) = f(a) \vdash f^5(a) = f^3(a)} C \quad \frac{f^3(a) = f(a) \vdash f^3(a) = f(a)}{f^3(a) = f(a) \vdash f^5(a) = f(a)} Ax}{f^3(a) = f(a) \vdash f^5(a) = f(a)} T$$

Show soundness and completeness of TEL.

Show that TEL is decidable.

- Equational Logic is a heavily used fragment of first-order logic.
- It consists of term equalities $s = t$, with proof rules
 - 1 Reflexivity: $\frac{}{s=s}$
 - 2 Symmetry: $\frac{s=t}{t=s}$
 - 3 Transitivity: $\frac{r=s \quad s=t}{r=t}$
 - 4 Congruence: $\frac{s_1=t_1, \dots, s_n=t_n}{f(s_1, \dots, s_n)=f(t_1, \dots, t_n)}$
 - 5 Instantiation: $\frac{s=t}{\sigma(s)=\sigma(t)}$, for substitution σ .
- We say $\Gamma \vdash s = t$ when the equality $s = t$ can be derived from the equalities in Γ .
- Show that equational logic is sound and complete.

Use equational logic to formalize

- 1 Semigroups: A set G with an associative binary operator $.$
- 2 Monoids: A set M with associative binary operator $.$ and unit 1
- 3 Groups: A monoid with an right-inverse operator x^{-1}
- 4 Commutative groups and semigroups
- 5 Rings: A set R with commutative group $\langle R, +, -, 0 \rangle$, semigroup $\langle R, . \rangle$, and distributive laws $x.(y + z) = x.y + x.z$ and $(y + z).x = y.x + z.x$
- 6 Semilattice: A commutative semigroup $\langle S, \wedge \rangle$ with idempotence $x \wedge x = x$
- 7 Lattice: $\langle L, \wedge, \vee \rangle$ where $\langle L, \wedge \rangle$ and $\langle L, \vee \rangle$ are semilattices, and $x \vee (x \wedge y) = x$ and $x \wedge (x \vee y) = x$.
- 8 Distributive lattice: A lattice with $x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$.
- 9 Boolean algebra: Distributive lattice with constants 0 and 1 and unary operation $-$ such that $x \wedge 0 = 0$, $x \vee 1 = 1$, $x \wedge -x = 0$, and $x \vee -x = 1$.

- Prove that every group element has a left inverse.
- For a lattice, define $x \leq y$ as $x \wedge y = x$. Show that \leq is a partial order (reflexive, transitive, and antisymmetric).
- Show that a distributive lattice satisfies $x \vee (y \wedge z) = (x \vee y) \wedge (x \vee z)$.
- Prove the de Morgan laws, $\neg(x \vee y) = \neg x \wedge \neg y$ and $\neg(x \wedge y) = \neg x \vee \neg y$ for Boolean algebras.

We can now complete the transition to first-order logic by adding

$$\begin{aligned} \tau & := && \color{red}{X} \\ & \quad | && f(\tau_1, \dots, \tau_n), \text{ for } n \geq 0 \\ \phi & := && \neg\phi \mid \phi_1 \vee \phi_2 \mid \phi_1 \wedge \phi_2 \mid \tau_1 = \tau_2 \\ & \quad | && \color{red}{\forall x.\phi \mid \exists x.\phi \mid q(\tau_1, \dots, \tau_n), \text{ for } n \geq 0} \end{aligned}$$

Terms contain variables, and formulas contain atomic and quantified formulas.

$M[q]$ is a map from D^n to $\{\top, \perp\}$, where n is the arity of predicate q .

$$M[x]\rho = \rho(x)$$

$$M[q(a_1, \dots, a_n)]\rho = M[q](M[a_1]\rho, \dots, M[a_n]\rho)$$

$$M[\forall x.A]\rho = \begin{cases} \top, & \text{if } M[A]\rho[x := d] \text{ for all } d \in D \\ \perp, & \text{otherwise} \end{cases}$$

$$M[\exists x.A]\rho = \begin{cases} \top, & \text{if } M[A]\rho[x := d] \text{ for some } d \in D \\ \perp, & \text{otherwise} \end{cases}$$

Atomic formulas are either equalities or of the form $q(a_1, \dots, a_n)$.

	Left	Right
\forall	$\frac{\Gamma, A[t/x] \vdash \Delta}{\Gamma, \forall x.A \vdash \Delta}$	$\frac{\Gamma \vdash A[c/x], \Delta}{\Gamma \vdash \forall x.A, \Delta}$
\exists	$\frac{\Gamma, A[c/x] \vdash \Delta}{\Gamma, \exists x.A \vdash \Delta}$	$\frac{\Gamma \vdash A[t/x], \Delta}{\Gamma \vdash \exists x.A, \Delta}$

- Constant c must be chosen to be new so that it does not appear in the conclusion sequent.
- Demonstrate the soundness of first-order logic.
- A theory consists of a signature Σ for the function and predicate symbols and non-logical axioms.
- If a T is obtained from S by extending the signature and adding axioms, then T is conservative with respect to S , if all the formulas in S provable in T are also provable in S .

Using First-Order Logic

- Prove $\exists x.(p(x) \Rightarrow \forall y.p(y))$.
- Give at least two satisfying interpretations for the statement $(\exists x.p(x)) \implies (\forall x.p(x))$.
- A sentence is a formula with no free variables. Find a sentence A such that both A and $\neg A$ are satisfiable.
- Write a formula asserting the unique existence of an x such that $p(x)$.
- Define operations for collecting the free variables $vars(A)$ in a given formula A , and substituting a term a for a free variable x in a formula A to get $A\{x \mapsto a\}$.
- Is $M[A\{x \mapsto a\}]\rho = M[A]\rho[x := M[a]\rho]$? If not, show an example where it fails. Under what condition does the equality hold?
- Show that any quantified formula is equivalent to one in *prenex normal form*, i.e., where the only quantifiers appear at the head of the formula and the body is purely a propositional combination of atomic formulas.

- Prove

- 1 $\neg\forall x.A \iff \exists x.\neg A$

- 2 $(\forall x.A \wedge B) \iff (\forall x.A) \wedge (\forall x.B)$

- 3 $(\exists x.A \vee B) \iff (\exists x.A) \vee (\exists x.B)$

- 4 $((\forall x.A) \vee (\forall x.B)) \Rightarrow (\forall x.A \vee B)$

- Write the axioms for a partially ordered relation \leq .
- Write the axioms for a bijective (1-to-1, onto) function f .
- Write a formula asserting that for any x , there is a unique y such that $p(x, y)$.
- Can you write first-order formulas whose models
 - 1 Have exactly (at most, at least) three elements?
 - 2 Are infinite
 - 3 Are finite but unbounded
- Can you write a first-order formula asserting that
 - 1 A relation is transitively closed
 - 2 A relation is the transitive closure of another relation.

- Thus far, variables ranged over ordinary datatypes such as numbers, and the functions and predicates were fixed (constants).
- Second-order logic allows free and bound variables to range over the functions and predicates of first-order logic.
- In n 'th-order logic, the arguments (and results) of functions and predicates are the functions and predicates of m 'th-order logic for $m < n$.
- This kind of strong typing is required for consistency, otherwise, we could define $R(x) = \neg x(x)$, and derive $R(R) = \neg R(R)$.
- Higher-order logic, which includes n 'th-order logic for any $n > 0$, can express a number of interesting concepts and datatypes that are not expressible within first-order logic: transitive closure, fixpoints, finiteness, etc.

Types in Higher-Order Logic

- Base types: e.g., `bool`, `nat`, `real`
- Tuple types: $[T_1, \dots, T_n]$ for types T_1, \dots, T_n .
- Tuple terms: (a_1, \dots, a_n)
- Projections: $\pi_i(a)$
- Function types: $[T_1 \rightarrow T_2]$ for domain type T_1 and range type T_2 .
- Lambda abstraction: $\lambda(x : T_1) : a$
- Function application: $f a$.

Semantics of Higher Order Types

$$\llbracket \text{bool} \rrbracket = \{0, 1\}$$

$$\llbracket \text{real} \rrbracket = \mathbf{R}$$

$$\llbracket [T_1, \dots, T_n] \rrbracket = \llbracket T_1 \rrbracket \times \dots \times \llbracket T_n \rrbracket$$

$$\llbracket [T_1 \rightarrow T_2] \rrbracket = \llbracket T_2 \rrbracket^{\llbracket T_1 \rrbracket}$$

Higher-Order Proof Rules

β -reduction	$\frac{\Gamma \vdash (\lambda(x : T) : a)(b) = a[b/x], \Delta}{\Gamma \vdash (\lambda(x : T) : a)(b) = a[b/x], \Delta}$
Extensionality	$\frac{\Gamma \vdash (\forall(x : T) : f(x) = g(x)), \Delta}{\Gamma \vdash f = g, \Delta}$
Projection	$\frac{\Gamma \vdash \pi_i(a_1, \dots, a_n) = a_i, \Delta}{\Gamma \vdash \pi_i(a_1, \dots, a_n) = a_i, \Delta}$
Tuple Ext.	$\frac{\Gamma \vdash \pi_1(a) = \pi_1(b), \Delta, \dots, \Gamma \vdash \pi_n(a) = \pi_n(b), \Delta}{\Gamma \vdash a = b, \Delta}$

Using Higher-Order Logic

- Define universal quantification using equality in higher-order logic.
- Express and prove Cantor's theorem (there is no injection from a type T to a $[T \rightarrow bool]$) in higher-order logic.
- Write the induction principle for Peano arithmetic in higher-order logic.
- Write a definition for the transitive closure of a relation in higher-order logic.
- Describe the modal logic CTL in higher-order logic.
- State and prove the Knaster-Tarski theorem.

Completeness of First-Order Logic

- The quantifier rules for sequent calculus require copying.
- Proof branches can be extended without bound.
- Ex: Show that LK is sound: $\vdash A$ implies $\models A$.
- The Henkin closure $H(\Gamma)$ is the smallest extension of a set of sentences Γ that is Henkin-closed, i.e., contains $B \Rightarrow A(c_B)$ for every $B \in H(\Gamma)$ of the form $\exists x : A$. (c_B is a fresh constant.)
- Any consistent set of formulas Γ has a *consistent* Henkin closure $H(\Gamma)$.
- As before, any consistent, Henkin closed set of formulas Γ has a complete, Henkin-closed extension $\widehat{\Gamma}$.
- Ex: Construct an interpretation $M_{\widehat{H(\Gamma)}}$ from $\widehat{H(\Gamma)}$ and show that it is a model for Γ .

Herbrand's Theorem

- For any sentence A there is a quantifier-free sentence A_H (the Herbrand form of A) such that $\vdash A$ in LK iff $\vdash A_H$ in TEL_0 .
- The Herbrand form is a *dual* of Skolemization where each universal quantifier is replaced by a term $f(\bar{y})$, where \bar{y} is the set of governing existentially quantified variables.
- Then, $\exists x : (p(x) \Rightarrow \forall y : p(y))$ has the Herbrand form $\exists x.p(x) \Rightarrow p(f(x))$, and the two formulas are equi-valid.
- How do you prove the latter formula?

Herbrand's Theorem

- Herbrand terms are those built from function symbols in A_H (adding a constant, if needed).
- Show that if A_H is of the form $\exists \bar{x}. B$, then $\vdash A_H$ iff $\bigvee_{i=0}^n \sigma_i(B)$, for some Herbrand term substitutions $\sigma_1, \dots, \sigma_n$.
- [Hint: In a cut-free sequent proof of a prenex formula, the quantifier rules can be made to appear below all the other rules. Such proofs must have a quantifier-free mid-sequent above which the proof is entirely equational/propositional.]
- Show that if a formula has a counter-model, then it has one built from Herbrand terms (with an added constant if there isn't one).

- Consider a formula of the form $\forall x.\exists y.q(x, y)$.
- It is equisatisfiable with the formula $\forall x.q(x, f(x))$ for a new function symbol f .
- If $M \models \forall x.\exists y.q(x, y)$, then for any $c \in |M|$, there is $d_c \in |M|$ such that $M \models q(x, y) \{x \mapsto c, y \mapsto d_c\}$. let M' extend M so that $M'(f)(c) = d_c$, for each $c \in |M|$: $M' \models \forall x.q(x, f(x))$.
- Conversely, if $M \models \forall x.q(x, f(x))$, then for every $c \in |M|$, $M \models q(x, y) \{x \mapsto c, y \mapsto M(f)(c)\}$.
- Prove the general case that any prenex formula can be Skolemized by replacing each existentially quantified variable y by a term $f(\bar{x})$, where f is a distinct, new function symbol for each y , and \bar{x} are the universally quantified variables governing y .

Unification

- A substitution is a map $\{x_1 \mapsto a_1, \dots, x_n \mapsto a_n\}$ from a finite set of variables $\{x_1, \dots, x_n\}$ to a set of terms.
- Define the operation $\sigma(a)$ of applying a substitution (such as the one above) to a term a to replace any free variables x_i in t with a_i .
- Define the operation of composing two substitutions $\sigma_1 \circ \sigma_2$ as $\{x_1 \mapsto \sigma_1(a_1), \dots, x_n \mapsto \sigma_1(a_n)\}$, if σ_2 is of the form $\{x_1 \mapsto a_1, \dots, x_n \mapsto a_n\}$.
- Given two terms $f(x, g(y, y))$ and $f(g(y, y), x)$ (possibly containing free variables), find a substitution σ such that $\sigma(a) \equiv \sigma(b)$.
- Such a σ is called a unifier.
- Not all terms have such unifiers, e.g., $f(g(x))$ and $f(x)$.
- A substitution σ_1 is more general than σ_2 if the latter can be obtained as $\sigma \circ \sigma_1$, for some σ .
- Define the operation of computing the most general unifier, if there is one, and reporting failure, otherwise.

Resolution Example

- To prove $(\exists y.\forall x.p(x, y)) \Rightarrow (\forall x.\exists y.p(x, y))$
- Negate: $(\exists y.\forall x.p(x, y)) \wedge (\exists x.\forall y.\neg p(x, y))$
- Prenexify: $\exists y_1.\forall x_1.\exists x_2.\forall y_2.p(x_1, y_1) \wedge \neg p(x_2, y_2)$
- Skolemize: $\forall x_1, y_2.p(x_1, c) \wedge \neg p(f(x_1), y_2)$
- Distribute and clausify: $\{p(x_1, c), \neg p(f(x_3), y_2)\}$
- Unify and resolve with unifier $\{x_1 \mapsto f(x_3), y_2 \mapsto c\}$
- Yields an empty clause
- Now try to show $(\forall x.\exists y.p(x, y)) \Rightarrow (\exists y.\forall x.p(x, y))$.

Dedekind–Peano Arithmetic

- The natural numbers consist of $0, s(0), s(s(0)),$ etc.
- Clearly, $0 \neq s(x)$, for any x .
- Also, $s(x) = s(y) \Rightarrow x = y$, for any x and y .
- Next, we would like to say that this is all there is, i.e., every domain element is reachable from 0 through applications of s .
- This requires induction:
 $P(0) \wedge (\forall n. P(n) \Rightarrow P(n+1)) \Rightarrow (\forall n. P(n))$, for every property P .
- But there is no way to write this — there are uncountably many properties (subset of natural numbers) but only finitely many formulas.
- Induction is therefore given as a scheme, an infinite set of axioms, with the template

$$A\{x \mapsto 0\} \wedge (\forall x. A \Rightarrow A\{x \mapsto s(x)\}) \Rightarrow (\forall x. A).$$

- We still need to define $+$ and \times . **How?**
- How do you define the relations $x < y$ and $x \leq y$?

- Prove that

- 1 $\forall x. x = 0 \vee (\exists y. s(y) = x)$
- 2 $\forall x, y, z. (x + y) + z = x + (y + z)$
- 3 $\forall x, y. x + y = y + x$
- 4 $\forall x, y. x < y \implies \neg(y < x)$

Set theory can be axiomatized using axiom schemes, using a membership relation \in :

- Extensionality: $x = y \iff (\forall z. z \in x \iff z \in y)$
- The existence of the empty set $\forall x. \neg x \in \emptyset$
- Pairs: $\forall x, y. \exists z. \forall u. u \in z. \iff u = x \vee u = y$ (Define the singleton set containing the empty set. Construct a representation for the ordered pair of two sets.)
- Union: How? (Define a representation for the finite ordinals using singleton, or using singleton and union.)
- Separation: $\{x \in y \mid A\}$, for any formula A , $y \notin \text{vars}(A)$. (Define the intersection and disjointness of two sets.)
- Infinity: There is a set containing all the finite ordinals.
- Power set: For any set, we have the set of all its subsets.
- Regularity: Every set has an element that is disjoint from it.
- Replacement: There is a set that is a superset of the image Y of a set X with respect to a functional $(\forall x \in X. \exists! y. A(x, y))$ rule $A(x, y)$.

- Can two different sets be empty?
- For your definition of ordered pairing, define the first and second projection operations.
- Define the Cartesian product $x \times y$ of two sets, as the set of ordered pairs $\langle u, v \rangle$ such that $u \in x$ and $v \in y$.
- Define a subset of $x \times y$ to be functional if it does not contain any ordered pairs $\langle u, v \rangle$ and $\langle u, v' \rangle$ such that $v \neq v'$.
- Define the function space y^x of the functions that map elements of x to elements of y .
- Define the join of two relations, where the first is a subset of $x \times y$ and the second is a subset of $y \times z$.

- Can all mathematical truths (valid sentences) be formally proved?
- *No*. There are valid statements about numbers that have no proof. (Gödel's first incompleteness theorem)
- Suppose Z is some formal theory claiming to be a sound and complete formalization of arithmetic, i.e., it proves all and only valid statements about numbers.
- Gödel showed that there is a valid but unprovable statement.

The First Incompleteness Theorem

- The expressions of Z can be represented as numbers as can the proofs.
- The statement “ p is a proof of A ” can then be represented by a formula $Pf(x, y)$ about numbers x and y .
- If p is represented by the number \underline{p} and A by \underline{A} , then $Pf(\underline{p}, \underline{A})$ is provable iff p is a proof of A .
- Numbers such as \underline{A} are representable as numerals in Z and these numerals can also be represented by numbers, $\underline{\underline{A}}$.
- Then $\exists x.Pf(x, y)$ says that the statement represented by y is *provable*. Call this $Pr(y)$.

The Undecidable Sentence

- Let $S(x)$ represent the numeric encoding of the operation such that for any number k , $S(k)$ is the encoding of the expression obtained by substituting the numeral for k for the variable 'x' in the expression represented by the number k .
- Then $\neg Pr(S(x))$ is represented by a number k , and the undecidable sentence U is $\neg Pr(S(k))$.
- \underline{U} is $S(k)$, i.e., the sentence obtained by substituting the numeral for k for 'x' in $\neg Pr(S(x))$ which is represented by k .
- Since U is $\neg Pr(\underline{U})$, we have a situation where either
 - 1 U , i.e., $\neg Pr(\underline{U})$, is provable, but from the numbering of the proof of U , we can also prove $Pr(\underline{U})$.
 - 2 $\neg U$, i.e., $Pr(\underline{U})$ is provable, but clearly none of $Pf(0, \underline{U})$, $Pf(1, \underline{U})$, \dots , is provable (since otherwise U would be provable), an ω -inconsistency, or
 - 3 Neither U nor $\neg U$ is provable: an incompleteness.

Second Incompleteness Theorem

- The negation of the sentence U is Σ_1 , and Z can verify Σ_1 -completeness (every *valid* Σ_1 -sentence is *provable*).
- Then

$$\vdash Pr(\underline{U}) \Rightarrow Pr(\underline{Pr(\underline{U})}).$$

- But this says $\vdash Pr(\underline{U}) \Rightarrow Pr(\underline{\neg U})$.
- Therefore $\vdash Con(Z) \Rightarrow \neg Pr(\underline{U})$.
- Hence $\neg \vdash Con(Z)$, by the first incompleteness theorem.
- **Exercise:** The theory Z is consistent if $A \wedge \neg A$ is not provable for any A . Show that ω -consistency is stronger than consistency. Show that the consistency of Z is adequate for proving the first incompleteness theorem.

Floyd's method for Flowchart programs

- A flowchart has a *start* vertex with a single outgoing edge, a *halt* vertex with a single incoming edge.
- Each vertex corresponds to a program block or a decision conditions.
- Each edge corresponds to an assertion; the start edge is the flowchart *precondition*, and the halt edge is the flowchart *postcondition*.
- *Verification conditions* check that for each vertex, each incoming edge assertion through the block implies the outgoing edge assertion.
- *Partial correctness*: If each verification condition has been discharged, then every halting computation starting in a state satisfying the precondition terminates in a state satisfying the postcondition.
- *Total correctness*: If there is a ranking function mapping states to ordinals that strictly decreases for any cycle in the flowchart, then every computation terminates in the halt

Floyd's Method

```
max = 0;
i = 0;
{ $i \leq N \wedge \forall(j < i): a[j] \leq \max$ }
while (i < N){
  if (a[i] > max){
    max = a[i];
  }
  i++;
}
{ $\forall(j < N): a[j] \leq \max$ }
```

Precondition is true, and postcondition is $\forall(j < N): a[j] \leq \max$.
The *loop invariant* is $i \leq N \wedge \forall(j < i): a[j] \leq \max$.

- A Hoare triple has the form $\{P\}S\{Q\}$, where S is a program statement in terms of the program variables drawn from the set Y and P and Q are assertions containing logical variables from X and program variables.
- A program statement is one of
 - 1 A *skip* statement *skip*.
 - 2 A *simultaneous assignment* $\bar{y} := \bar{e}$ where \bar{y} is a sequence of n distinct program variables, e is a sequence of n $\Sigma[Y]$ -terms.
 - 3 A *conditional* statement $e ? S_1 : S_2$, where C is a $\Sigma[Y]$ -formula.
 - 4 A *loop while e do S*.
 - 5 A sequential composition $S_1; S_2$.

Skip	$\{P\}skip\{P\}$
Assignment	$\{P[\bar{e}/\bar{y}]\}\bar{y} := \bar{e}\{P\}$
Conditional	$\frac{\{C \wedge P\}S_1\{Q\} \quad \{\neg C \wedge P\}S_2\{Q\}}{\{P\}C ? S_1 : S_2\{Q\}}$
Loop	$\frac{\{P \wedge C\}S\{P\}}{\{P\}while\ C\ do\ S\{P \wedge \neg C\}}$
Composition	$\frac{\{P\}S_1\{R\} \quad \{R\}S_2\{Q\}}{\{P\}S_1; S_2\{Q\}}$
Consequence	$\frac{P \Rightarrow P' \quad \{P'\}S\{Q'\} \quad Q' \Rightarrow Q}{\{P\}S\{Q\}}$

- Both assertions and statements contain operations from a first-order signature Σ .
- An assignment σ maps program variables in Y to values in $dom(M)$.
- A program expression e has value $M[e]\sigma$.
- The meaning of a statement $M[S]$ is given by a sequence of states (of length at least 2).
 - 1 $\sigma \circ \sigma \in M[skip]$, for any state σ .
 - 2 $\sigma \circ \sigma[M[\bar{e}]\sigma/\bar{y}] \in M[\bar{y} := \bar{e}]$, for any state σ .
 - 3 $\psi_1 \circ \sigma \circ \psi_2 \in M[S_1; S_2]$ for $\psi_1 \circ \sigma \in M[S_1]$ and $\sigma \circ \psi_2 \in M[S_2]$
 - 4 $\psi \in M[C ? S_1 : S_2]$ if either $M[C]\psi[0] = \top$ and $\psi \in M[S_1]$, or $M[C]\psi[0] = \perp$ and $\psi \in M[S_2]$
 - 5 $\sigma \circ \sigma \in M[while\ C\ do\ S]$ if $M[C]\sigma = \perp$
 - 6 $\psi_1 \circ \sigma \circ \psi_2 \in M[while\ C\ do\ S]$ if $M[C](\psi_1[0]) = \top$, $\psi_1 \circ \sigma \in M[S]$, and $\sigma \circ \psi_2 \in M[while\ C\ do\ S]$

- $\{P\}S\{Q\}$ is *valid* in a Σ -structure M if for every sequence $\sigma \circ \psi \circ \sigma' \in M[[S]]$ and any assignment ρ of values in $dom(M)$ to logical variables in X , either
 - 1 $M[[Q]]_{\sigma'}^{\rho} = \top$, or
 - 2 $M[[P]]_{\sigma}^{\rho} = \perp$.
- Informally, every computation sequence for S either ends in a state satisfying Q or starts in a state falsifying P .
- **Demonstrate the soundness of the Hoare calculus.**

Completeness of Hoare Logic

- The proof of a valid triple $\{P\}S\{Q\}$ can be decomposed into
 - 1 The valid triple $\{wlp(S)(Q)\}S\{Q\}$, and
 - 2 The valid assertion $P \Rightarrow wlp(S)(Q)$
- $wlp(S)(Q)$ (the *weakest liberal precondition*) is an assertion such that for any $\psi \in M[S]$ with $|\psi| = n + 1$ and ρ , either $M[Q]_{\psi_n}^\rho = \perp$ or $M[wlp(S)(Q)]_{\psi_0}^\rho = \top$.
- Show that for any S and Q , the valid triple $\{wlp(S)(Q)\}S\{Q\}$ can be proved in the Hoare calculus. (Hint: Use induction on S .)
- First-order arithmetic over $\langle +, \cdot, 0, 1 \rangle$ is sufficient to express $wlp(S)(Q)$ since it can code up sequences of states representing computations.

Transition Systems: Mutual Exclusion

initially

`try[1] = critical[1] = turn = false`

transition

```
¬try[1] → try[1] := true;
        turn := false;
¬try[2] ∨ turn → critical[1] := true;
critical[1] → critical[1] := false;
              try[1] := false;
```

||

initially

`try[2] = critical[2] = false`

transition

```
¬try[2] → try[2] := true;
        turn := true;
¬try[1] ∨ ¬turn → critical[2] := true;
critical[2] → critical[2] := false;
              try[2] := false;
```

Model Checking Transition Systems

- A transition system is given as a triple $\langle W, I, N \rangle$ of states W , an initialization predicate I , and a transition relation N .
- Symbolic Model Checking: Fixpoints such as $\mu X. I \sqcup post(N)(X)$ which is the set of reachable states can be constructed as an ROBDD.
- Bounded Model Checking: $I(s_0) \wedge \bigwedge_{i=0}^k N(s_i, s_{i+1})$ represents the set of possible $(k + 1)$ -step computations and $\neg P(s_{k+1})$ represents the possible violations of state predicate P at the state s_{k+1} .
- k -Induction: A variant of bounded model checking can be used to prove properties:
 - Base: Check that P holds in the first k states of the computation
 - Induction: If P holds for any sequence of k steps in a computation, it holds in the $k + 1$ -th state.
- Prove the mutual exclusion property by k -induction.

- Interpolation: The unsatisfiability of the BMC query yields an interpolant Q such that $I(s_0) \wedge N(s_0, s_1)$ and $\bigwedge_{i=1}^k N(s_i, s_{i+1}) \wedge \neg P(s_{k+1})$ are jointly unsatisfiable.
- The proof yields an interpolant $Q(s_1)$.
- Let $I'(s_0)$ be $I(s_0) \vee Q(s_0)$.
- If $I(s_0) = I'(s_0)$ then this is an invariant. Otherwise, repeat the process with I replaced by I' .
- Prove the mutual exclusion property using interpolation-based model checking.

Conclusions: Speak Logic!

- Logic is a powerful tool for
 - ① Formalizing concepts
 - ② Defining abstractions
 - ③ Proving validities
 - ④ Solving constraints
 - ⑤ Reasoning by calculation
 - ⑥ Mechanized inference
- The power of logic is when it is used as an aid to effective reasoning.
- *Logic can become enormously difficult, and it would undoubtedly be well to produce more assurance in its use. . . . We may some day click off arguments on a machine with the same assurance that we now enter sales on a cash register.*

Vannevar Bush, As We May Think

- The machinery of logic has made it possible to solve large and complex problems; formal verification is now a practical technology.
